Preface xiii
Preface to first edition xvii

1 Introduction 1

1.1 Linear antennas 1
1.2 Maxwell’s equations and the potential functions 3
1.3 Power and the Poynting vector 5
1.4 The field of thin linear antennas: general equations 7
1.5 The field of the electrically short antenna; directivity 11
1.6 The field of antennas with sinusoidally distributed currents; radiation resistance 13
1.7 Impedance of antenna: EMF method 16
1.8 Integral equations for the current distribution 20
1.9 Direct numerical methods 23

2 An approximate analysis of the cylindrical antenna 31

2.1 The sinusoidal current 31
2.2 The equation for the current 32
2.3 Properties of integrals 33
2.4 Rearranged equation for the current 36
2.5 Reduction of integral equation to algebraic equation 36
2.6 Evaluation of coefficients 39
2.7 The approximate current and admittance 40
2.8 Numerical examples; comparison with experiment 41
2.9 The radiation field 43
2.10 An approximate two-term theory 48
2.11 The receiving antenna 50
# Contents

## 3 The two-element array

- 3.1 The method of symmetrical components 54
- 3.2 Properties of integrals 57
- 3.3 Reduction of integral equations for phase sequences to algebraic equations 59
- 3.4 The phase-sequence currents and admittances 62
- 3.5 Currents for arbitrarily driven antennas; self- and mutual admittances and impedances 64
- 3.6 Currents for one driven, one parasitic antenna 66
- 3.7 The couplet 67
- 3.8 Field patterns 68
- 3.9 The two-term approximation 70

## 4 The circular array

- 4.1 Integral equations for the sequence currents 80
- 4.2 Sequence functions and array properties 86
- 4.3 Self- and mutual admittances 88
- 4.4 Currents and fields; arrays with one driven element 95
- 4.5 Matrix notation and the method of symmetrical components 103
- 4.6 General formulation and solution 107

## 5 The circuit and radiating properties of curtain arrays

- 5.1 Comparison of conventional and two-term theories 112
- 5.2 Two-term theory of curtain arrays 114
- 5.3 Example: the three-element array 124
- 5.4 Electronically scanned arrays 128
- 5.5 Examples of the general theory for large arrays 137
- 5.6 The special case when \( \beta_0 h = \pi / 2 \) 148
- 5.7 Summary 151

## 6 Arrays with unequal elements: parasitic and log-periodic antennas

- 6.1 Application of the two-term theory to a simple parasitic array 153
- 6.2 The problem of arrays with parasitic elements of unequal lengths 160
- 6.3 Application to the Yagi–Uda array 162
## Contents

6.4 Evaluation of coefficients for the Yagi–Uda array 167  
6.5 Arrays with half-wave elements 170  
6.6 The far field of the Yagi–Uda array; gain 173  
6.7 Simple applications of the modified theory; comparison with experiment 179  
6.8 The three-element Yagi–Uda array 182  
6.9 The four and eight director Yagi–Uda arrays 190  
6.10 Receiving arrays 198  
6.11 Driven arrays of elements that differ greatly in length 208  
6.12 The log-periodic dipole array 215  
6.13 Analysis of the log-periodic dipole array 216  
6.14 Characteristics of a typical log-periodic dipole array 222  
6.15 Frequency-independent properties of the log-periodic dipole array 228  
6.16 Experimental verification of the theory for arrays of unequal dipoles 239

### 7 Planar and three-dimensional arrays

7.1 Vector potentials and integral equations for the currents 241  
7.2 Vector potential differences and integral equations 245  
7.3 Approximate distribution of current 247  
7.4 Evaluation of coefficients 249  
7.5 The field patterns 253  
7.6 The general two-element array 256  
7.7 A simple planar array 262  
7.8 A three-dimensional array of twenty-seven elements 272  
7.9 Electrical beam scanning 284  
7.10 Problems with practical arrays 288

### 8 Vertical dipoles on and over the earth or sea

8.1 Introduction 290  
8.2 The complete electromagnetic field of a vertical dipole over the earth or sea with or without a coating 292  
8.3 The field in the air in the intermediate range 296  
8.4 The far field in the air 298  
8.5 Base-driven and grounded monopoles 303  
8.6 Vertical antennas on the earth for communicating with submarines in the ocean 308  
8.7 High-frequency dipoles over the earth; cellular telephone 314  
8.8 Vertical dipoles over a two-layered region 321
Contents

8.9 Propagation over the spherical earth 327
8.10 Conclusion 341

9 Dipoles parallel to the plane boundaries of layered regions; horizontal dipole over, on, and in the earth or sea 343

9.1 Introduction 343
9.2 Horizontal traveling-wave antennas over earth or sea; Beverage antenna ($l = 0, \epsilon = k_0/k_2$) 349
9.3 The terminated insulated antenna in earth or sea 357
9.4 Arrays of horizontal and vertical antennas over the earth 359
9.5 Horizontal antennas over the spherical earth 365
9.6 Horizontal electric dipoles for remote sensing on and in the earth, sea, or Arctic ice 369
9.7 Horizontal electric dipoles and patch antennas on microstrip 372

10 Application of the two-term theory to general arrays of parallel non-staggered elements 379

10.1 Brief derivation of the formulas 379
10.2 The complete two-term theory formulas 384
10.3 Remarks and programming considerations 385
10.4 Alternative form for the solution and the case $kh = \pi/2$ 390

11 Resonances in large circular arrays of perfectly conducting dipoles 392

11.1 Introduction 392
11.2 The two-term theory and the modified kernel 396
11.3 Phase-sequence resonances 399
11.4 Behavior near a phase-sequence resonance 403
11.5 Radiation field at or near a phase-sequence resonance 405
11.6 Refinements for numerical calculations 408
11.7 Resonant array with two driven elements 409
11.8 Appendix: the various kernels for the circular array 420

12 Resonances in large circular arrays of highly conducting dipoles 425

12.1 Introduction 425

1 Introduction

1.1 Linear antennas

Wireless communication depends upon the interaction of oscillating electric currents in specially designed, often widely separated configurations of conductors known as antennas. Those considered in this book consist of thin metal wires, rods or tubes arranged in arrays. Electric charges in the conductors of a transmitting array are maintained in systematic accelerated motion by suitable generators that are connected to one or more of the elements by transmission lines. These oscillating charges exert forces on other charges located in the distant conductors of a receiving array of elements of which at least one is connected by a transmission line to a receiver. Fundamental quantities which describe such interactions are the electromagnetic field, the driving-point admittance, and the driving-point impedance. These can be easily determined if the distributions of current on the array elements are known. The determination of the currents on the array elements is the main concern of this book. In this first chapter, the basic electromagnetic equations are formulated and applied to a single antenna in free space. The simplest approach of assuming the current rather than actually determining it is reviewed first. Then, integral equations for the current distributions are derived, and determining the current by numerical methods is discussed. These discussions serve as an introduction to the analytical theory of antennas and arrays based on the solution of integral equations that is presented in subsequent chapters.

Figures 1.1a and 1.1b show two simple practical radiating systems. In Fig. 1.1a, a section at the open end of a two-wire transmission line has been bent outward to form a dipole antenna. In Fig. 1.1b, the inner conductor of a coaxial transmission line is extended above a ground plane. In both cases, the transmission lines are connected to generators which oscillate at a frequency \( f = \omega / 2 \pi \). In a small region (comparable in extent with the distance between the two conductors of the transmission line), the antenna and line are coupled. Owing to the complications involved in this coupling, it is convenient to replace the actual generator/transmission line with an idealized so-called delta-function generator, which maintains an impressed electric field \( \mathbf{E}^\delta(z) = \hat{z} E^\delta(z) = V \delta(z) \hat{z} \) at the surface of the antenna. This is the linear antenna of Fig. 1.1c. The impressed field is non-zero only at the center \( z = 0 \) of the cylindrical surface. The delta-function generator is an independent voltage source in the sense of ordinary
Introduction

To generator

Ground plane

To generator

Figure 1.1 (a) Dipole antenna and two-wire transmission line. (b) Monopole antenna over a ground plane. (c) Simplified center-driven linear antenna.

circuit theory. The linear antenna of Fig. 1.1c can also serve as a model for other types of radiating systems. The simplifying assumption of studying the antenna in the absence of the connecting transmission line is particularly useful when the antenna is an array element.

The radius of the linear dipole antenna of Fig. 1.1c is \( a \), and its half-length is \( h \). It is assumed throughout this book that the radius is much smaller than both the wavelength \( \lambda \) and the length \( 2h \) of the antenna. Under such conditions, one can neglect the small currents on the capped ends of the antenna and assume that only a current

\[
K_z(z) = \frac{I(z)}{2\pi a}
\]

is maintained on the cylindrical surface of the antenna. Other concepts of circuit theory can be introduced, and are particularly useful to the antenna engineer: the driving-point admittance \( Y_0 \) and driving-point impedance \( Z_0 \) are defined as

\[
Y_0 = G_0 + jB_0 = \frac{I(0)}{V} = \frac{1}{Z_0^*}, \quad Z_0 = R_0 + jX_0 = \frac{V}{I(0)} = \frac{1}{Y_0^*}. \tag{1.1}
\]

\( G_0, B_0, R_0, \) and \( X_0 \) are respectively, the driving-point conductance, susceptance, resistance, and reactance. When \( h, a, \) and \( f \) are such that the antenna is at resonance, one has \( X_0 = 0 \) and \( B_0 = 0 \). As an example of the use of these quantities in a practical situation, consider the problem of designing the antenna so that, at a given frequency \( f \), there is maximum power transfer from a transmission line of given characteristic impedance \( Z_c \). With the assumption that the transmission line and the antenna can be studied separately, the problem is reduced to that of determining \( h \) and \( a \) so that \( Z_0 \) is equal to \( Z_c^* \), the complex conjugate of \( Z_c \).

The delta function \( \delta(z) \) is zero except when \( z = 0 \). Additional, well-known properties of the delta function are

\[
\delta(z) = \begin{cases} 
0, & \text{if } z \neq 0 \\
\infty, & \text{if } z = 0
\end{cases}, \quad \int_{-b}^{b} \delta(z) \, dz = 1 \tag{1.2a}
\]
1.2 Maxwell’s equations and potential functions

\[ \delta(kz) = \frac{1}{|k|} \delta(z), \quad f(z)\delta(z) = f(0)\delta(z) \quad (1.2b) \]

\[ \int_{-b}^{b} f(z)\delta(z) \, dz = f(0) \quad (1.2c) \]

\[ \frac{d}{dz} H(z) = \delta(z) \quad \text{where} \quad H(z) = \begin{cases} 1, & \text{if } z > 0 \\ 0, & \text{if } z < 0. \end{cases} \quad (1.2d) \]

In (1.2), \( b \) is any positive constant, \( k \) is any real constant, \( f(z) \) is any smooth function of \( z \), and \( H(z) \) is the step function.

The interaction of charges and currents is governed by Maxwell’s equations which define the electromagnetic field. With an assumed time dependence \( e^{j\omega t} \), they are

\[ \nabla \times \mathbf{B} = \mu_0 (\mathbf{J} + j\omega\epsilon_0 \mathbf{E}), \quad \nabla \cdot \mathbf{B} = 0 \quad (1.3a) \]

\[ \nabla \times \mathbf{E} = -j\omega\mathbf{B}, \quad \nabla \cdot \mathbf{E} = \rho/\epsilon_0, \quad (1.3b) \]

where the electric vector \( \mathbf{E} \) is in volts per meter (V/m), the magnetic vector \( \mathbf{B} \) in tesla (T). SI units are used throughout this book. The volume density of current \( \mathbf{J} \) in amperes per square meter (A/m²) is the charge crossing unit area per second. The volume density of charge \( \rho \) is in coulombs per cubic meter (C/m³). \( \mathbf{J} \) and \( \rho \) satisfy the equation of continuity,

\[ \nabla \cdot \mathbf{J} + j\omega\rho = 0. \quad (1.3c) \]

In the interior of perfect conductors, \( \mathbf{J} = 0 \) and \( \rho = 0 \). In (1.3), \( \epsilon_0 \) and \( \mu_0 \) are the absolute permittivity and permeability of free space. They have the numerical values \( \epsilon_0 = 8.854 \times 10^{-12} \) farads per meter (F/m) and \( \mu_0 = 4\pi \times 10^{-7} \) henrys per meter (H/m), and are related to the velocity \( c \) of light and the characteristic impedance \( \zeta_0 \) of free space by

\[ c = \frac{1}{\sqrt{\mu_0\epsilon_0}}, \quad \zeta_0 = \sqrt{\frac{\mu_0}{\epsilon_0}}. \quad (1.4) \]

Transmission lines and antennas are made from highly conducting materials such as brass or copper. In most cases, it is an excellent approximation to assume that the
conductors are perfect. The relevant boundary conditions at an interface between a
perfect conductor and air are

\[ \mathbf{n} \times \mathbf{E} = 0, \quad \mathbf{n} \cdot \mathbf{E} = \eta / \varepsilon_0 \] 
\[ (1.5a) \]
\[ \mathbf{n} \times \mathbf{B} = \mu_0 \mathbf{K}, \quad \mathbf{n} \cdot \mathbf{B} = 0. \] 
\[ (1.5b) \]

In (1.5), \( \mathbf{n} \) is the unit normal to the conductor–air interface. Its direction is outward
from the conductor to the air. \( \mathbf{K} \) is the surface density of current in amperes per meter
(A/m) and \( \eta \) is the surface density of charge in coulombs per square meter (C/m²)
on the perfect conductor. The left-hand equation in (1.5a) states that the component
of the electric field in air tangent to the surface of the perfect conductor must be
zero. The left-hand equation in (1.5b) states that the tangential magnetic field in air
is proportional to the surface density of current on the conductor.

It is convenient to introduce the scalar and vector potentials \( \phi \), \( \mathbf{A} \). The defining
relationships between the potentials and the electromagnetic-field vectors are obtained
with the aid of Maxwell's equations. With the vector identity \( \nabla \cdot (\nabla \times \mathbf{C}) = 0 \) (where
\( \mathbf{C} \) is any vector) and the equation \( \nabla \cdot \mathbf{B} = 0 \), the magnetic field may be expressed in
the form

\[ \mathbf{B} = \nabla \times \mathbf{A}. \] 
\[ (1.6) \]

If (1.6) is substituted in (1.3b), it follows that

\[ \nabla \times (\mathbf{E} + j \omega \mathbf{A}) = 0. \] 
\[ (1.7) \]

The identity \( \nabla \times (\nabla \psi) = 0 \), where \( \psi \) is a scalar function, then permits the definition
of \( \phi \) in the form

\[ -\nabla \phi = \mathbf{E} + j \omega \mathbf{A}. \] 
\[ (1.8) \]

The substitution of (1.6) and (1.8) into the remaining Maxwell equations leads
to coupled partial differential equations for \( \mathbf{A} \) and \( \phi \). They can be decoupled if the following condition relating \( \mathbf{A} \) and \( \phi \) is imposed:

\[ \nabla \cdot \mathbf{A} = -j \omega \mu_0 \varepsilon_0 \phi \quad \text{or} \quad \nabla \cdot \mathbf{A} = -j \frac{\beta_0^2 \phi}{\omega}, \] 
\[ (1.9) \]

where the free-space wave number \( \beta_0 \) (also denoted by \( k \) in this book) is given by

\[ \beta_0 = \omega \sqrt{\mu_0 \varepsilon_0} = \frac{\omega}{c} = \frac{2\pi}{\lambda} \] 
\[ (1.10) \]

and \( \lambda \) is the free-space wavelength. Equation (1.9) is known as the Lorentz condition.
The resulting equations for \( \mathbf{A} \) and \( \phi \) are

\[ (\nabla^2 + \beta_0^2) \mathbf{A} = -\mu_0 \mathbf{J}, \quad (\nabla^2 + \beta_0^2) \phi = -\rho / \varepsilon_0. \] 
\[ (1.11) \]
The solutions to (1.11) can be derived with the use of the retarded Green’s function. They are

\[ A(r) = \frac{\mu_0}{4\pi} \int J(r') e^{-j\beta_0 |r - r'|} dV' \]

(1.12a)

and

\[ \phi(r) = \frac{1}{4\pi \epsilon_0} \int \rho(r') e^{-j\beta_0 |r - r'|} dV', \]

(1.12b)

where the volume integrations extend over the entire region occupied by currents or charges. In most cases considered in this book, the conductors are perfect so that only surface current densities \( K \) and surface charge densities \( \eta \) are present. In such cases, the volume integrals in (1.12) reduce to surface integrals. In the limit of infinitely thin wire antennas, the surface integrals in turn reduce to line integrals.

### 1.3 Power and the Poynting vector

The complex Poynting vector is defined as

\[ S = \frac{1}{2\mu_0} E \times B^*, \]

(1.13)

where the asterisk denotes the complex conjugate. The integral of the normal component of \( \text{Re}(S) \) over a closed surface \( \Sigma \) is the time-average, total power transferred from within \( \Sigma \). The time average is over a period \( T = 2\pi/\omega \). Several useful identities
involving the Poynting vector are now derived. The geometry of interest is shown in Fig. 1.2. A perfect conductor surrounded by air is shown. The conductor–air interface is the closed surface $\Sigma_0$, and $\mathbf{n}_0$ is the unit outward normal. Assume that there is an impressed electric field $\mathbf{E}_t$ tangent to the surface of the conductor. As a result, a surface current density $\mathbf{K}$ exists on the conductor’s surface. This, in turn, maintains an electromagnetic field $\mathbf{E}$ and $\mathbf{B}$ in the air. The total electric field on the conductor’s surface is $\mathbf{E} + \mathbf{E}_t$, and the boundary conditions on the surface of the perfect conductor are

$$\mathbf{n}_0 \times (\mathbf{E} + \mathbf{E}_t) = 0, \quad \mathbf{n}_0 \times \mathbf{B} = \mu_0 \mathbf{K}. \quad (1.14)$$

Suppose that $\Sigma_1$ is a closed (mathematical) surface in the air surrounding the perfect conductor, and that $\mathbf{n}_1$ is the corresponding unit normal vector. Let $\tau_{01}$ be the volume lying between $\Sigma_0$ and $\Sigma_1$, and consider the quantity

$$\int_{\tau_{01}} \nabla \cdot \mathbf{S} \, dV. \quad (1.15)$$

First, with (1.13), the vector identity

$$\nabla \cdot (\mathbf{E} \times \mathbf{B}^*) = \mathbf{B}^* \cdot (\nabla \times \mathbf{E}) - \mathbf{E} \cdot (\nabla \times \mathbf{B}^*) \quad (1.16)$$

and the Maxwell equations on the left in (1.3a, b), it is seen that

$$\int_{\tau_{01}} \nabla \cdot \mathbf{S} \, dV = - j \omega \int_{\tau_{01}} (\frac{1}{2} \mu_0^{-1} |\mathbf{B}|^2 - \frac{1}{2} \epsilon_0 |\mathbf{E}|^2) \, dV. \quad (1.17)$$

The boundaries of the volume $\tau_{01}$ are the surfaces $\Sigma_0$ and $\Sigma_1$. Application of the divergence theorem to the quantity in (1.15) yields

$$\int_{\tau_{01}} \nabla \cdot \mathbf{S} \, dV = - \int_{\Sigma_0} (\mathbf{n}_0 \cdot \mathbf{S}) \, d\Sigma + \int_{\Sigma_1} (\mathbf{n}_1 \cdot \mathbf{S}) \, d\Sigma. \quad (1.18)$$

A comparison of (1.17) and (1.18) yields the identity

$$\int_{\Sigma_1} (\mathbf{n}_1 \cdot \mathbf{S}) \, d\Sigma = \int_{\Sigma_0} (\mathbf{n}_0 \cdot \mathbf{S}) \, d\Sigma - j \omega \int_{\tau_{01}} (\frac{1}{2} \mu_0^{-1} |\mathbf{B}|^2 - \frac{1}{2} \epsilon_0 |\mathbf{E}|^2) \, dV. \quad (1.19a)$$

If one takes the real part of this equation, no volume integral appears:

$$P \equiv \int_{\Sigma_0} (\mathbf{n}_0 \cdot \text{Re}(\mathbf{S})) \, d\Sigma = \int_{\Sigma_1} (\mathbf{n}_1 \cdot \text{Re}(\mathbf{S})) \, d\Sigma. \quad (1.19b)$$

Equation (1.19b) states that $P$, the total time-average power entering $\Sigma_0$, is the same as the total time-average power leaving $\Sigma_1$.

The next identity of interest is obtained by expressing $\int_{\Sigma_0} (\mathbf{n}_0 \cdot \mathbf{S}) \, d\Sigma$ in (1.19a) in terms of $\mathbf{E}_t$ and $\mathbf{K}$. With (1.13), the vector identity $\mathbf{n}_0 \cdot (\mathbf{E} \times \mathbf{B}^*) = - \mathbf{E} \cdot (\mathbf{n}_0 \times \mathbf{B}^*)$,
1.4 Field of thin linear antennas

and the boundary conditions (1.14), it is seen that \( \int_{\Sigma_0} (\hat{n}_0 \cdot \mathbf{S}) \, d\Sigma = \int_{\Sigma_0} \frac{1}{2} \mathbf{E}^r \cdot \mathbf{K}^r \, d\Sigma \) so that (1.19a) can be written as

\[
\int_{\Sigma_0} \frac{1}{2} \mathbf{E}^r \cdot \mathbf{K}^r \, d\Sigma = j\omega \int_{\tau_0} \left( \frac{1}{2} \mu_0^{-1} |\mathbf{B}|^2 - \frac{1}{2} \varepsilon_0 |\mathbf{E}|^2 \right) \, dV + \int_{\Sigma_1} (\hat{n}_1 \cdot \mathbf{S}) \, d\Sigma. \tag{1.20a}
\]

The real part of this expression is

\[
P \equiv \int_{\Sigma_0} \text{Re}\{\frac{1}{2} \mathbf{E}^r \cdot \mathbf{K}^r\} \, d\Sigma = \int_{\Sigma_1} (\hat{n}_1 \cdot \text{Re}\{\mathbf{S}\}) \, d\Sigma. \tag{1.20b}
\]

In (1.20), \( \Sigma_1 \) is any surface completely surrounding the air–conductor interface \( \Sigma_0 \). Equations (1.20a, b) can be extended to surfaces \( \Sigma_1 \) that pass through the surface of the perfect conductor, provided that \( \mathbf{E}^r = 0 \) on any part of \( \Sigma_0 \) excluded by \( \Sigma_1 \). This follows from the boundary condition \( \hat{n}_0 \times \mathbf{E} = 0 \) on the part of \( \Sigma_0 \) excluded by \( \Sigma_1 \) and the fact that all fields are zero within the volume occupied by the perfect conductor.

Equation (1.20b) states that the time-average power transferred to the perfect conductor from the “generator” (i.e. the impressed electric field \( \mathbf{E}^e \)) is all radiated into free space. Equations (1.20a, b) possess analogues for the case of imperfect conductors; these involve a volume integral instead of a surface integral, and include a term due to the ohmic losses in the conductors. It is important to note that in both (1.19) and (1.20), only integrations of \( \hat{n} \cdot \mathbf{S} \) over closed surfaces appear; it is not mathematically justified to attach meaning to an integral of \( \hat{n} \cdot \mathbf{S} \) over only a part of a closed surface.

Consider the limiting case of an infinitely thin, perfectly conducting wire lying on the \( z \)-axis between \(-h \) and \( h \). The impressed electric field is \( E^e_z(z) \), and the current on the wire is \( I(z) \). In this limit, (1.20b) reduces to

\[
P \equiv \int_{-h}^{h} \text{Re}\{\frac{1}{2} E^e_z(z) I^r(z)\} \, dz = \int_{\Sigma_1} (\hat{n}_1 \cdot \text{Re}\{\mathbf{S}\}) \, d\Sigma. \tag{1.20c}
\]

1.4 The field of thin linear antennas: general equations

Now consider the linear antenna of Fig. 1.1c and assume that \( a \ll h \) and \( \beta_0 a \ll 1 \). Both cylindrical coordinates \( \rho, \Phi, z \) and spherical coordinates \( r, \Theta, \Phi \) are to be used throughout this book. Rotational symmetry obtains, so that all cylindrical or spherical field components are independent of \( \Phi \). There is a surface current density \( K_z(z) \) on the cylindrical surface \( \rho = a \), and also a current on the small capped ends of the antenna. The latter currents can be neglected when calculating the field of the antenna. The total current \( I(z) \) and the charge per unit length \( q(z) \) are defined to be

\[
I(z) = 2\pi a K_z(z), \quad q(z) = 2\pi a \eta(z). \tag{1.21}
\]
They are related by the one-dimensional equation of continuity

$$\frac{dI(z)}{dz} = -j\omega q(z).$$  \hspace{1cm} (1.22)

$I(z)$ is even with respect to $z$ and $q(z)$ is odd.

When calculating the field of the antenna, one can assume that the current is located at the axis $z = 0$, which is the same as replacing the antenna of radius $a$ by an infinitely thin antenna. With this assumption, but without reference to a particular current distribution $I(z)$, formulas for calculating the field are given in this section and some general characteristics of the field are discussed. The coordinate system is shown in Fig. 1.3.

It is seen from (1.12a) that $\mathbf{A} = \mathbf{\hat{z}} A_z(\rho, z)$. Equations (1.12a, b) reduce to

$$A_z = \frac{\mu_0}{4\pi} \int_{-h}^{h} I(z') \frac{e^{-j\beta_0 R}}{R} dz'$$  \hspace{1cm} (1.23a)

and

$$\phi = \frac{1}{4\pi \epsilon_0} \int_{-h}^{h} q(z') \frac{e^{-j\beta_0 R}}{R - dz'},$$  \hspace{1cm} (1.23b)

where $R = |\mathbf{r} - \mathbf{\hat{z}} z'|$ is the distance from a point $z'$ on the infinitely thin antenna to the
1.4 Field of thin linear antennas

observation point \( \mathbf{r} \). The one-dimensional Lorentz condition is

\[
\frac{\partial A_z}{\partial z} = -j \frac{\beta_0^2}{\omega} \phi. \tag{1.23c}
\]

The \( \mathbf{E} \) and \( \mathbf{B} \) fields are obtained from (1.6) and (1.8) with (1.23a) and (1.23c). In the cylindrical coordinates \( \rho, \Phi, z \), they are

\[
\mathbf{B} = \hat{\Phi} B_\Phi \quad \text{and} \quad \mathbf{E} = \hat{\rho} E_\rho + \hat{z} E_z,
\]

where

\[
B_\Phi = -\frac{\partial A_z}{\partial \rho}, \tag{1.24a}
\]

\[
E_\rho = -j \omega \frac{\beta_0^2}{\rho^3} \frac{\partial A_z}{\partial \rho}, \tag{1.24b}
\]

\[
E_z = -j \omega \frac{\beta_0^2}{\rho^3} \left( \frac{\partial^2 A_z}{\partial z^2} + \beta_0^2 A_z \right). \tag{1.24c}
\]

In the spherical coordinates \( r, \Theta, \Phi \) with origin at the center of the antenna, the electric field is given by

\[
E_r = E_z \cos \Theta + E_\rho \sin \Theta, \tag{1.25a}
\]

\[
E_\Theta = -E_z \sin \Theta + E_\rho \cos \Theta. \tag{1.25b}
\]

At sufficiently great distances from the antenna \( r^2 \gg h^2 \) and \( (\beta_0 r)^2 \gg 1 \), the field reduces to a simple form known as the radiation or far field. It is given by

\[
B'_\Phi = E'_\Theta / c, \tag{1.26a}
\]

where

\[
E' = E'_\Theta \hat{\Theta}, \quad E'_\Theta = \frac{j \omega \mu_0}{4 \pi} \sin \Theta \int_{-h}^{h} I(\zeta') e^{-j \beta_0 R} d\zeta'. \tag{1.26b}
\]

The distance \( R \) from an arbitrary point on the antenna to the field point is given in terms of \( r \) and \( z' \) by the cosine law, namely (Fig. 1.3),

\[
R = \sqrt{r^2 + z'^2 - 2 r z' \cos \Theta}. \tag{1.27a}
\]

In the radiation zone, \( r^2 \gg z'^2 \). If the binomial expansion is applied to (1.27a) and only the linear term in \( z' \) is retained, the following approximate form is obtained for \( R \):

\[
R \approx r - z' \cos \Theta, \quad (\beta_0 r)^2 \gg 1. \tag{1.27b}
\]

The phase variation of \( \exp(-j \beta_0 R) / R \) is replaced with the linear phase variation given by (1.27b), i.e. by \( \exp(-j \beta_0 r + j \beta_0 z' \cos \Theta) \). The amplitude \( 1 / R \) of \( \exp(-j \beta_0 R) / R \) is a slowly varying function of \( z' \) and is replaced by \( 1 / r \), where \( r \) is the distance to the center of the antenna. With these approximations, (1.26b) can be written as

\[
E'_\Theta = \frac{j \zeta_0 I(0)}{2 \pi} \frac{e^{-j \beta_0 r}}{r} F_0(\Theta, \beta_0 h), \tag{1.28a}
\]
where \( \zeta_0 = \sqrt{\mu_0 / \epsilon_0} \approx 120\pi \) ohms and

\[
F_0(\Theta, \beta_0 h) = \frac{\beta_0 \sin \Theta}{2I(0)} \int_{-h}^{h} I(z') e^{j\beta_0 z' \cos \Theta} dz'. \tag{1.28b}
\]

The term \( F_0(\Theta, \beta_0 h) \) contains all the directional properties of a linear radiator of length \( 2h \). It is called the field characteristic, field factor, or element factor, and will be computed for some commonly used current distributions. The magnetic field \( B' \) in the far zone is at right angles to \( E' \) and also perpendicular to the direction of propagation \( r \). It is given by (1.26a). Thus

\[
B' = \hat{\Phi} B'_{\Phi}, \quad B'_{\Phi} = \frac{j\mu_0 I(0)}{2\pi} \frac{e^{-j\beta_0 r}}{r} F_0(\Theta, \beta_0 h). \tag{1.28c}
\]

Note that the field in the far zone depends on \( F_0(\Theta, \beta_0 h) \) which is a function of the particular distribution of current in the antenna.

It is instructive to consider the instantaneous value of the field in (1.28a), which is obtained by multiplication with \( e^{j\omega t} \) and selection of the real part. Except for a phase factor,

\[
E'(\Theta, r, t) = \text{Re} E(\Theta)(r)e^{j\omega t} \sim \frac{\sin(\omega t - \beta_0 r)}{r} = \frac{\sin \omega(t - r/c)}{r}. \tag{1.29a}
\]

Note that the field at the point \( r \) at the instant \( t \) is computed from the current at \( r = 0 \) at the earlier time \( (t - r/c) \). This is a consequence of the finite velocity of propagation \( c \).

The equiphase and equipotential surfaces of \( E \) and \( B \) are spherical shells on which \( r \) is equal to a constant. There are an infinite number of such shells that have the same phase (differ by an integral multiple of \( 2\pi \)) but only one that has both the same amplitude and the same phase. The velocity of propagation is the outward radial velocity of the surfaces of constant phase where the phase is represented by the argument of the sine term in (1.29a), that is

\[
\text{phase} = \Psi = \omega t - \beta_0 r. \tag{1.29b}
\]

For a constant phase

\[
\frac{d\Psi}{dt} = 0 = \omega - \beta_0 \frac{dr}{dt}. \tag{1.29c}
\]

It follows that

\[
\frac{dr}{dt} = \frac{\omega}{\beta_0} = c = 3 \times 10^8 \text{ m/s}. \tag{1.29d}
\]

Since the phase repeats itself every \( 2\pi \) radians, a wavelength is the distance between two adjacent equiphase surfaces. For example, if one surface is defined by \( r = r_1 \) and the other by \( r = r_2 \), then

\[
\omega t - \beta_0 r_1 = 2\pi \quad \text{and} \quad \omega t - \beta_0 r_2 = 4\pi \tag{1.30a}
\]
1.5 Field of electrically short antenna

The field of the electrically short antenna; directivity

If the current on a thin linear antenna is known, the far-field pattern can be easily determined from the equations in the previous section. When the antenna is electrically short, i.e. \( \beta_0 a \ll \beta_0 h \ll 1 \), the plausible assumption that the current distribution is triangular can be made. This assumed current distribution is adequate for calculating the field, even quite close to the antenna.

A diagram of the triangular distribution is shown in Fig. 1.4, where the magnitude of the current is plotted along an axis perpendicular to the antenna. In order to find a simple expression for the radiation field, the exponent in (1.28b) can be approximated by 1. Thus,

\[
F_0(\Theta, \beta_0 h) \approx \frac{\beta_0 \sin \Theta}{2} \int_{-h}^{h} \left( 1 - \frac{|z|}{h} \right) dz = \frac{\beta_0 h \sin \Theta}{2}; \quad (\beta_0 h)^2 \ll 1. \quad (1.31)
\]

Equation (1.31) shows that the radiation field of a short linear antenna is proportional to \( \sin \Theta \). Polar and rectangular graphs of the field are shown in Figs. 1.5a and 1.5b, normalized with respect to the maximum at \( \Theta = 90^\circ \).
The field quite near an electrically short antenna is readily evaluated from (1.23a) with $I(z) = I(0)(1 - |z|/h)$ and $R \approx r$. This gives

$$A_z = \frac{\mu_0 h I(0)}{4\pi} e^{-j\beta_0 r} \left(1 - \frac{|z|}{h}\right).$$  \hfill (1.32)

The components of the field can be evaluated in the spherical coordinates $r, \Theta, \Phi$ from (1.6) and (1.3a). The results are

$$B_\Theta = \frac{\xi_0 h I(0)}{4\pi} \left(\frac{j\beta_0}{r} + \frac{1}{r^2}\right) e^{-j\beta_0 r} \sin \Theta.$$  \hfill (1.33a)

$$E_r = \frac{\zeta_0 h I(0)}{4\pi} \left(\frac{2}{r^2} - \frac{j2}{\beta_0 r^3}\right) e^{-j\beta_0 r} \cos \Theta.$$  \hfill (1.33b)

$$E_\Theta = \frac{j\xi_0 h I(0)}{4\pi} \left(\frac{\beta_0}{r} - \frac{j}{r^2} - \frac{1}{\beta_0 r^3}\right) e^{-j\beta_0 r} \sin \Theta.$$  \hfill (1.33c)

These may be expressed in terms of the dipole moment $p_z = I(0)h/j\omega$ if desired. The electromagnetic power transferred across a closed surface in the far zone is given by the integral of $Re\{S_r\} \sim \sin^2 \Theta$. An angular graph of $Re\{S_r\}$ is called a power.
Antennas with sinusoidal currents

The half-power beam width $\Theta_{hp}$ is defined as the angular distance between half-power points on the radiation pattern referred to the principal lobe. The value of $\Theta_{hp}$ for the short linear antenna is $90^\circ$. Another parameter useful in defining the directive properties of an antenna is the absolute directivity $D$. This parameter is a measure of the total time-average power transferred across a closed surface in the direction of the principal lobe. The time-average power transferred across a closed surface $\Sigma$ is the integral of the normal component of $S$. Thus, in the far zone,

$$P = \int_{\Sigma} S_{r} \, d\Sigma.$$  \hfill (1.34)

The directivity $D$ is the ratio of $P$ with $S_{r}$ set at its maximum value $S_{r}^{\text{max}}$ to the actual value of $P$. For a short dipole with $|S_{r}| \sim \sin^2 \Theta$, the value of $D$ is

$$D = \frac{4\pi}{\int_{0}^{2\pi} \int_{0}^{\pi} \sin^2 \Theta \sin \Theta \, d\Theta} = \frac{3}{2}. \hfill (1.35)$$

A nearly omnidirectional pattern requires a large value of $\Theta_{hp}$ and a nearly unity value of $D$. A more directional pattern requires a smaller value of $\Theta_{hp}$ and a larger value of $D$.

The field of antennas with sinusoidally distributed currents; radiation resistance

It is customary to assume that the current distribution on a linear antenna is sinusoidal, i.e.

$$I(\xi) = \frac{I(0) \sin \beta_0 (h - |\xi|)}{\sin \beta_0 h} = I_m \sin \beta_0 (h - |\xi|). \hfill (1.36)$$

For this current, the field characteristic $F_0(\Theta, \beta_0 h)$ is given by (1.28b) with (1.36),

$$F_0(\Theta, \beta_0 h) = \frac{\cos(\beta_0 h \cos \Theta) - \cos \beta_0 h}{\sin \beta_0 h \sin \Theta}. \hfill (1.37a)$$

An alternative field characteristic $F_m(\Theta, \beta_0 h)$ is referred to the maximum value of the sinusoid, namely, $I_m = I(0)/\sin \beta_0 h$ which occurs at $h = \lambda/4$ when $\beta_0 h \geq \pi/2$.

$$F_m(\Theta, \beta_0 h) = \frac{\cos(\beta_0 h \cos \Theta) - \cos \beta_0 h}{\sin \Theta}. \hfill (1.37b)$$

The function $F_m(\Theta, \beta_0 h)$ is shown graphically in Fig. 1.6 for several values of $h$. It is seen that the pattern corresponding to $\beta_0 h = \pi/2$ ($h = \lambda/4$) is only slightly narrower.
Figure 1.6  Field factor of linear antenna.

than the pattern for $(\beta_0 h)^2 \ll 1$ which is shown in Fig. 1.5b. Note that as $\beta_0 h$ is increased beyond $\pi$, minor lobes appear which successively become the major lobe and point in directions other than $\Theta = \pi/2$.

The theoretical model of an infinitely thin antenna with a sinusoidal distribution of current is a convenient one: the complete electromagnetic field can be evaluated
1.6 Antennas with sinusoidal currents

exactly in terms of elementary functions, even for observation points arbitrarily close to the antenna. This is accomplished with the substitution of the current (1.36) in the general integral (1.23a) for the vector potential, and subsequent use of the resulting expression in (1.24). The indicated differentiations can be carried out directly without evaluating the integral. The result is

\[ B_{\phi}(\rho, z) = \frac{jI m}{4\pi\rho} \left[ e^{-j\beta_0 R_{1h}} + e^{-j\beta_0 R_{2h}} - 2 \cos \beta_0 h \ e^{-j\beta_0 r} \right] \]  

(1.38a)

\[ E_{\rho}(\rho, z) = \frac{jI m \zeta_0}{4\pi\rho} \left[ \frac{z-h}{R_{1h}} e^{-j\beta_0 R_{1h}} + \frac{z+h}{R_{2h}} e^{-j\beta_0 R_{2h}} - \frac{2z}{r} \cos \beta_0 h \ e^{-j\beta_0 r} \right] \]  

(1.38b)

\[ E_z(\rho, z) = -\frac{jI m \zeta_0}{4\pi} \left[ \frac{e^{-j\beta_0 R_{1h}}}{R_{1h}} + \frac{e^{-j\beta_0 R_{2h}}}{R_{2h}} - 2 \cos \beta_0 h \ e^{-j\beta_0 r} \right] \]  

(1.38c)

\[ B_{\rho}(\rho, z) = B_z(\rho, z) = E_{\phi}(\rho, z) = 0, \]  

(1.38d)

where

\[ r = \sqrt{\rho^2 + z^2}, \quad R_{1h} = \sqrt{\rho^2 + (h-z)^2}, \quad R_{2h} = \sqrt{\rho^2 + (h+z)^2} \]  

(1.38e)

are the distances from the observation point to the center and the two ends of the antenna, respectively.

When \( \beta_0 h = \pi/2 \), the interpretation of (1.38) in terms of spheroidal waves is available in [1, pp. 297–310] or [3, Chapter V]. It is easily checked that, when \( r \) is large, (1.38a–d) reduce to the radiation field given by (1.28a, c) with (1.37a).

Furthermore, (1.38) are seen to reduce to the field (1.33) of the electrically short antenna when \( \beta_0 h \ll 1 \).

The total, time-average power \( P \) is equal to the integral of the normal component of \( \text{Re}\{S\} = (1/2\mu_0) \text{Re}\{E \times B^*\} \) over a closed surface surrounding the antenna, where \( E \) and \( B \) are given by (1.38). Although any closed surface completely surrounding the antenna will correctly give \( P \), it is convenient to select a large sphere for the integration surface and use the expressions (1.28) and (1.37) for the radiation field in spherical coordinates. The complete formula for \( P \) determined in this manner can be found, for example, in [2, p. 140]. It is easy to see that the expression for \( P \) has the form

\[ P = \frac{1}{2} |I_m|^2 R_m^e \quad \text{or} \quad P = \frac{1}{2} |I(0)|^2 R_0^e \]  

(1.39)

where the quantities \( R_m^e \) and \( R_0^e = R_m^e / \sin^2 \beta_0 h \) depend only on \( \beta_0 h \). The units of \( R_m^e \) and \( R_0^e \) are ohms. By definition, \( R_m^e (R_0^e) \) is the radiation resistance referred to \( I_m (I(0)) \). \( R_m^e \) is equal to 73.1 ohms when \( \beta_0 h = \pi/2 \), and 199 ohms when \( \beta_0 h = \pi \).

In general, \( R_0^e \) is not the driving-point resistance of a center-driven antenna. To see why this is true, let us examine in more detail the model of an infinitely thin antenna with a sinusoidal distribution of current. In particular, in what way can one maintain, at least in principle, the sinusoidal current distribution (1.36) on the infinitely thin, perfectly conducting wire?
From (1.38c), it is seen that the exact tangential electric field \( E_z(0, z) \) on the wire’s axis is non-zero along the entire length of the wire. This is the axial field maintained by the sinusoidal current distribution, and not the total axial field. Since the total axial field is zero, there must be an externally maintained field \( E_e z = -E_z(0, z) \) on the perfectly conducting wire. It is given by

\[
E_e z(z) = \frac{j I_m \zeta_0}{4\pi} \left[ \frac{e^{-j\beta_0(h-z)}}{h-z} + \frac{e^{-j\beta_0(h+z)}}{h+z} - 2\cos \beta_0 h \frac{e^{-j\beta_0|z|}}{|z|} \right]; \quad -h < z < h
\]

and is non-zero along the whole length of the wire. It follows that it is not possible to excite a sinusoidal current simply by a single delta-function generator with \( E_e z(z) = V\delta(z) \). Instead, a continuous distribution of electromotive forces is necessary.

Equations (1.40), (1.36), and the power identity (1.20c) provide another equivalent way to determine the time-average power \( P \) radiated by the infinitely thin antenna, by integrating \( \text{Re} \left\{ \frac{1}{2} E_e z(z) I^*(z) \right\} \) along the length of the antenna. Note that the integrand is finite. As before, \( R_0^e \) is the coefficient of \( \frac{1}{2} |I(0)|^2 \) in the resulting expression.

The foregoing discussion clearly shows that \( R_0^e \) and the driving-point resistance \( R_0 \) of a center-driven antenna are two different quantities. In some cases, however, it is true that \( R_0 = R_0^e \). This will be seen in the next section.

1.7 Impedance of antenna: EMF method

In this section, the “induced EMF method” \([4]\) is discussed. This is an approximate method used for calculating the impedance of a center-driven antenna with non-zero radius.

Let \( I(z) = 2\pi a K_z(z) \) be the current on an antenna center-driven by a delta-function generator, and let \( E_z(a, z) \) be the tangential electric field at the surface \( \rho = a \). Consider the quantities

\[
-\frac{1}{|I(0)|^2} \int_{-h}^{h} E_z(a, z) I^*(z) \, dz
\]

or

\[
-\frac{1}{I^2(0)} \int_{-h}^{h} E_z(a, z) I(z) \, dz.
\]

These are both equal to \( Z_0 \), the driving-point impedance of the antenna. This is seen to be true by the substitution of the boundary condition \( E_z(a, z) = -V\delta(z) \) in (1.41) and the subsequent use of the property (1.2c) of the delta function and the definition \( Z_0 = V/I(0) \).
1.7 EMF method

The “induced EMF method” consists of determining the driving-point impedance of the antenna from the formula

\[ Z_0 = -\frac{1}{|I(0)|^2} \int_{-h}^{h} E_z(a, z) I^*(z) \, dz \]  

(1.41c)

where one uses the sinusoidal current distribution \( I(z) = [I(0)/\sin \beta_0 h] \sin \beta_0 (h - |z|) \) on the right-hand side, and the associated value of \( E_z(a, z) \) from (1.38c). It is easily seen from (1.38c) that the integral in (1.41c) is proportional to \( |I(0)|^2 \). Therefore, the final quantity obtained does not involve \( I(0) \); it is an integral expression which depends only on \( \beta_0 a \) and \( \beta_0 h \). Since \( I(z) \) is in phase with \( I(0) \) for all \( z \), the same result is obtained if (1.41b) is used instead of (1.41a).

The resulting integral expression for \( Z_0 \) can be evaluated by numerical integration, expressed [5] in terms of integrals tabulated in standard mathematical handbooks [6], or written in the form

\[ Z_0 = \frac{j \xi_0}{2\pi} \frac{1}{\sin^2 \beta_0 h} \left\{ \sin \beta_0 h \left[ C_a(h, h) - \cos \beta_0 h \ C_a(h, 0) \right] \right. \]

\[ - \cos \beta_0 h \left[ S_a(h, h) - \cos \beta_0 h \ S_a(h, 0) \right] \}, \]

(1.42a)

where the integrals \( C_a(h, z) \) and \( S_a(h, z) \), which occur frequently in antenna theory, are defined by

\[ C_a(h, z) = \int_0^h \cos \beta_0 z' \left[ e^{-j\beta_0 R_1} \frac{1}{R_1} + e^{-j\beta_0 R_2} \right] \, dz' \]  

(1.42b)

\[ S_a(h, z) = \int_0^h \sin \beta_0 |z'| \left[ e^{-j\beta_0 R_1} \frac{1}{R_1} + e^{-j\beta_0 R_2} \right] \, dz' \]  

(1.42c)

and where

\[ R_1 = \sqrt{(z - z')^2 + a^2}, \quad R_2 = \sqrt{(z + z')^2 + a^2}. \]  

(1.42d)

A short table of these integrals for the case \( a/\lambda = 0.007022 \) is given in [2, Appendix 1].

Note that the value of \( Z_0 \) so obtained is infinite when \( \beta_0 h = \pi, 2\pi, \ldots \). Therefore, the method cannot be used to determine the driving-point impedance of antennas with these lengths. Note also that, in the limit \( \beta_0 a \to 0 \), the value of \( R_0 = \text{Re}(Z_0) \) reduces to \( R_0^* \), where \( R_0^* \) is the radiation resistance obtained in the previous section.

From a theoretical point of view, the valid objection can be raised that two different models are involved in (1.41). These are the antenna in which a sinusoidal current distribution is maintained (by a continuous distribution of electromotive forces), and the antenna center-driven by a delta-function generator. Only under special circumstances can the first model be regarded as being similar to the second, or, indeed, to the more practical antennas of Figs. 1.1a and 1.1b. For the first model, there
Figure 1.7  Distribution of amplitude and phase of current in half-wave dipole.

is no single pair of terminals, so that the quantity in (1.41) is not the driving-point impedance of an antenna. For the second model, the quantity in (1.41) is indeed the driving-point impedance but (1.41c) is an identity, and not a means of determining $Z_0$. The electric field maintained by the currents in the first case violates the boundary condition $E_z(a, z) = 0 \ (z \neq 0)$ satisfied by the corresponding field in the case of the center-driven antenna.

In order to further understand the two models, it is instructive to consider the permissible choices of $\Sigma_1$ in (1.20b). In other words, for what types of surfaces $\Sigma_1$ does one correctly obtain the time-average power radiated? The answer is different for the two models: For the case of the center-driven antenna, $\Sigma_1$ can be any closed surface that encloses the delta-function generator at $z = 0$. It need not enclose the entire antenna. However, for the antenna with a sinusoidal distribution of current, it is necessary to enclose the entire antenna in order to correctly obtain $P$, the time-average power.

From an engineering point of view, the induced EMF method is best discussed by comparison with measurement. In order to obtain useful results, it is necessary that the assumed sinusoidal current distribution be close to the true current distribution, and that the antenna be electrically thin. Figures 1.7 and 1.8 show the measured amplitude and phase of the current for a base-driven monopole over a ground plane together with the sinusoidal current for $\beta_0 h = \frac{\pi}{2}$ and $\pi$, respectively. The parameter $\Omega$ is related to $h/a$ by $\Omega = 2 \ln(2h/a)$. In Fig. 1.7, the experimental data are taken from [7]. The
1.7 EMF method

Theoretical curve is in the form

\[
\frac{I(z)}{V} = \left| \frac{I(z)}{V} \right| e^{j\theta_{I}(z)} = \frac{I(0)}{V} \cos \beta_0 z = \frac{2}{Z_0} \cos \beta_0 z \tag{1.43}
\]

where \( Z_0 \) has been calculated from (1.41c) to be \( Z_0 = 73 + j41 \) ohms. The factor of 2 in the last equation in (1.43) is included so that \( I(z)/V \) corresponds to that of a monopole over a ground plane. In Fig. 1.8, the measurements have been made by Mack. The value of \( |I_m/V| = |I(\lambda/4)/V| \) in the theoretical curve is such that the total power radiated by the antenna with the sinusoidal current (as calculated from \( P = R_m |I_m|^2 \) with \( R_m = 199 \) ohms) is the same as the total power radiated by the base-driven monopole. The latter power can be found from the measured driving-point conductance \( G_0 = 1.023 \) millisiemens (mS) as \( P = G_0 |V|^2 \).

In Fig. 1.7, the general agreement between the measured values and the sinusoidal approximation is fair, with more current near the top of the actual antenna than is indicated by the cosine curve. The driving-point admittance as calculated by the induced EMF method agrees quite well with the measured value. The phase differs somewhat from the constant required by the sinusoidal distribution of current. For the full-wave antenna of Fig. 1.8, the sinusoidal current fails completely near the driving point, where, instead of \( |I(0)/V| = 0, |I(0)/V| \) is about three-quarters its maximum value along the antenna. The measured phase, instead of being constant, changes significantly along the antenna.

Some additional comments about the half-wave antenna are now made. More discussions along these lines can be found in [8]. For \( \beta_0 h = \pi/2 \), the measured current is fairly close to that predicted by the induced EMF method. It follows that the near-field \( B_\Phi \) should also be fairly close. This is not true, however, for all near-field
quantities. It follows from preceding discussions that the $E_z$ components are different. That the $E_\rho$ components should also be different is illustrated in Fig. 1.9, where the measured [7] charge per unit length $q(z)/V = |q(z)/V|e^{j\theta_0(z)}$ along the half-wave antenna is shown together with that predicted by the sinusoidal theory. The theoretical curve was calculated from (1.43) by the equation of continuity (1.22). Here, the agreement is quite poor.

The sinusoidal current distribution $\sin \beta_0(h - |z|)$ has been seen to be inadequate in many cases. Nevertheless, it is attractive because of its simplicity. In Chapter 2, linear antennas satisfying $\beta_0 a \ll \beta_0 h < 3\pi/2$ and $\beta_0 a \ll 1$ are considered. For such antennas, an improved representation of the current will be introduced. In this representation, $\sin \beta_0(h - |z|)$ is the first term, and the remaining terms are also simple trigonometric functions.

1.8 Integral equations for the current distribution

In the three preceding sections, the current distribution $I(z)$ along the length of the linear antenna has been assumed. A more scientific and more difficult method for investigating the properties of a center-driven linear antenna is to determine $I(z)$ from the boundary condition satisfied by $E_z$ on the surface of the antenna. If this condition is imposed, an integral equation for $I(z)$ results. A history of the development of the integral equation, as well as many additional references, can be found in [3, 9, 10].

This section first introduces the model of the center-driven tubular dipole. Two integral equations will be derived, one of which is exact for this model and will be called the exact integral equation. The second integral equation is approximate and
